
First-order methods in optimization - Evaluation

Olivier Leblanc, Guillaume Thiran.

1 Part 1 - Slide 45

1.1 6. (with code)

$$f(\mathbf{x}) = 2x_{[1]} + x_{[2]} = \max_{\mathbf{y}} \left\{ \sum_i y_i x_i; \sum_i y_i = 3, 0 \leq y_i \leq 2 \right\} = \sigma_{\{\mathbf{y} | \mathbf{1}^\top \mathbf{y} = 3, 0 \leq \mathbf{y} \leq 2\mathbf{1}\}}.$$

Hence,

$$\text{prox}_f(\mathbf{x}) = \mathbf{x} - \mathcal{P}_{\{\mathbf{y} | \mathbf{1}^\top \mathbf{y} = 3, 0 \leq \mathbf{y} \leq 2\mathbf{1}\}}(\mathbf{x}).$$

Writing $C = \{\mathbf{y} | \mathbf{1}^\top \mathbf{y} = 3, 0 \leq \mathbf{y} \leq 2\mathbf{1}\}$, it can be compared with $H_{\mathbf{a},b} \cap \text{Box}[\mathbf{l}, \mathbf{u}]$, with $\mathbf{a} = \mathbf{1}, b = 3, \mathbf{l} = \mathbf{0}, \mathbf{u} = 2$.

```
import numpy as np

def error_fct(a,b,l,u,x,mu):
    y = projbox(x-mu*a,l,u)
    error = a@y-b
    return error

def projbox(x, l, u):
    return np.minimum(np.maximum(x,l), u)

#projection on the intersection of an hyperplane and a box
def proj_H_inter_box(a,b,l,u,x):
    #start with guesses for mu-levels
    mu_low = -1
    mu_high = 1

    #check that the levels give respectively negative and positive values
    #for the function error = a@y-1 with y = proj_box(l,u,x-mu*a)

    #positive for low bound
    j=0
    j_max = 100
    error_l = -1
    while (error_l<0) & (j<j_max) :
        mu_low = mu_low*2 #more negative (always done in first iteration but not important)
        error_l=error_fct(a,b,l,u,x,mu_low)
        j=j+1

    #negative for low bound
    k=0
    k_max = 10
    error_h = 1
    while (error_h>0) & (k<k_max) :
        mu_high = mu_high*2 #more negative (always done in first iteration but not important)
        error_h=error_fct(a,b,l,u,x,mu_high)
        k=k+1

    #mu_low lead to positive value of the error,
    i = 0
    i_max = 100
    tol = 1e-8
    error = 2*tol
    while (np.abs(error)>tol) & (i<i_max) :
        mu_mid = (mu_low+mu_high)/2
        error = error_fct(a,b,l,u,x,mu_mid)

        if error>0:
            mu_low = mu_mid
        else:
            mu_high = mu_mid
```

```

        i=i+1

#Compute the solution with the good level
y= projbox(x-mu_mid*a,l,u)
return y

def proxf(x):
    return x - proj_H_inter_box(np.ones(len(x)),3,np.zeros(len(x)),2*np.ones(len(x)),x)

x = np.array([2,1,4,1,2,1])

print(proxf(x))

```

The output is : [1.5, 1., 2., 1., 1.5, 1.].

1.2 8.

$$f(t) = \begin{cases} 1/t, & t > 0, \\ \infty, & \text{else.} \end{cases}$$

$$\text{prox}_{\lambda f}(t) = \arg \min_u \begin{cases} \lambda/u, & u > 0, \\ \infty, & \text{else.} \end{cases} + \frac{1}{2} \|u - t\|_2^2$$

Hence,

$$\frac{-\lambda}{u^2} + u - t = 0 \Leftrightarrow u^3 - tu^2 - \lambda = 0.$$

Finally,

$$\text{prox}_{\lambda f}(t) = \{u > 0 | u^3 - tu^2 - \lambda = 0\}. \quad (1)$$

1.3 9.

$$f(\mathbf{X}) = \begin{cases} \text{tr } \mathbf{X}^{-1}, & \mathbf{X} \succ 0, \\ \infty, & \text{else.} \end{cases} = \begin{cases} \sum_{i=1}^n \frac{1}{\lambda_i}, & \mathbf{X} \succ 0, \\ \infty, & \text{else.} \end{cases}$$

As $\mathbf{X} \in \mathbb{S}^n$, it is a *spectral function*. Hence one can write $f(\mathbf{X}) = g(\lambda_1(\mathbf{X}), \dots, \lambda_n(\mathbf{X})) = \sum_{i=1}^n h(\lambda_i)$. With the Singular Value Decomposition (SVD) of \mathbf{X} as $\mathbf{X} = \mathbf{U} \text{diag } \lambda(\mathbf{X}) \mathbf{U}^T$, this gives

$$\begin{aligned} \text{prox}_{\lambda f}(\mathbf{X}) &= \mathbf{U} \text{diag}(\text{prox}_{\lambda g}[\lambda_1, \dots, \lambda_n]) \mathbf{U}^T \\ &= \mathbf{U} \text{diag}(\text{prox}_{\lambda h}(\lambda_1), \dots, \text{prox}_{\lambda h}(\lambda_n)) \mathbf{U}^T \\ &= \mathbf{U} \text{diag}(\{u > 0 | u^3 - \lambda_i u^2 - \lambda = 0\}) \mathbf{U}^T. \end{aligned}$$

1.4 10.

$$\lambda f(\mathbf{x}) = \lambda(\|\mathbf{x}\|_2 - 1)^2 = \lambda \|\mathbf{x}\|_2^2 - 2\lambda \|\mathbf{x}\|_2 + \lambda.$$

Using the provided tables, one identifies it with $g(\mathbf{x}) + \frac{c}{2} \|\mathbf{x}\|_2^2 + \langle \mathbf{a}, \mathbf{x} \rangle + \gamma$, with $g(\mathbf{x}) = -2\lambda \|\mathbf{x}\|_2$, $c = 2\lambda$, $\mathbf{a} = \mathbf{0}$, $\gamma = 0$. Hence,

$$\text{prox}_{\lambda f}(\mathbf{x}) = \text{prox}_{\frac{-2\lambda \|\cdot\|_2}{1+2\lambda}} \left(\frac{\mathbf{x}}{1+2\lambda} \right) = \begin{cases} \left(1 + \frac{2\lambda}{\|\mathbf{x}\|_2}\right) \frac{\mathbf{x}}{1+2\lambda}, & \mathbf{x} \neq \mathbf{0}, \\ \{\mathbf{u} : \|\mathbf{u}\| = \frac{2\lambda}{1+2\lambda}\}, & \mathbf{x} = \mathbf{0}. \end{cases}$$

2 Part 2 - Exercise 0 - slide 40

$$\min_{\mathbf{x} \in \mathbb{R}^n} \frac{1}{2} \|\mathbf{A}\mathbf{x} - \mathbf{b}\|_2^2 + \underbrace{\frac{\lambda_1}{2} \|\mathbf{x}\|_2^2 + \lambda_2 \|\mathbf{x}\|_1}_{\text{elastic net}},$$

where $\mathbf{A} \in \mathbb{R}^{m \times n}$, $\mathbf{b} \in \mathbb{R}^m$ and $\lambda_1, \lambda_2 > 0$. Choosing $f(\mathbf{x}) = \frac{1}{2} \|\mathbf{A}\mathbf{x} - \mathbf{b}\|_2^2 + \frac{\lambda_1}{2} \|\mathbf{x}\|_2^2$ as the σ -strongly convex and differentiable part and $g(\mathbf{x}) = \lambda_2 \|\mathbf{x}\|_1$ as the closed convex but non differentiable part, one has $\nabla f(\mathbf{x}) = \mathbf{A}^T(\mathbf{A}\mathbf{x} - \mathbf{b}) + \lambda_1 \mathbf{I}\mathbf{x}$ and $\text{prox}_{\alpha g}(\mathbf{x}) = \mathcal{T}_{\alpha \lambda_2}(\mathbf{x})$.

- (*Proximal Gradient*)

$$\begin{aligned}\mathbf{x}^{k+1} &= \text{prox}_{\frac{1}{L}g}(\mathbf{x}^k - \frac{1}{L}\nabla f(\mathbf{x}^k)) \\ &= \mathcal{T}_{\frac{\lambda_2}{L}}\left(\mathbf{x}^k - \frac{1}{L}(\mathbf{A}^\top \mathbf{A} + \lambda_1 \mathbf{I})\mathbf{x}^k + \frac{1}{L}\mathbf{A}^\top \mathbf{b}\right),\end{aligned}$$

with $L = \|\mathbf{A}^\top \mathbf{A} + \lambda_1 \mathbf{I}\| = \lambda_{\max}(\mathbf{A}^\top \mathbf{A}) + \lambda_1 = \|\mathbf{A}\|_2^2 + \lambda_1$.

- (*FISTA*)

$$\begin{cases} \mathbf{x}^{k+1} &= \mathcal{T}_{\frac{\lambda_2}{L}}\left(\mathbf{y}^k - \frac{1}{L}(\mathbf{A}^\top \mathbf{A} + \lambda_1 \mathbf{I})\mathbf{y}^k + \frac{1}{L}\mathbf{A}^\top \mathbf{b}\right) \\ t_{k+1} &= \frac{1+\sqrt{1+4t_k^2}}{2} \\ \mathbf{y}^{k+1} &= \mathbf{x}^{k+1} + \left(\frac{t_k-1}{t_{k+1}}\right)(\mathbf{x}^{k+1} - \mathbf{x}^k) \end{cases}$$

- (*V-FISTA*)

$$\begin{cases} \mathbf{x}^{k+1} &= \mathcal{T}_{\frac{\lambda_2}{L}}\left(\mathbf{y}^k - \frac{1}{L}(\mathbf{A}^\top \mathbf{A} + \lambda_1 \mathbf{I})\mathbf{y}^k + \frac{1}{L}\mathbf{A}^\top \mathbf{b}\right) \\ \mathbf{y}^{k+1} &= \mathbf{x}^{k+1} + \left(\frac{\sqrt{\kappa}-1}{\sqrt{\kappa}+1}\right)(\mathbf{x}^{k+1} - \mathbf{x}^k), \end{cases}$$

with $\kappa = L/\sigma$, and $\sigma = \lambda_{\min}(\mathbf{A}^\top \mathbf{A}) + \lambda_1 = \lambda_1$ if \mathbf{A} is not full rank.

Now, if one chooses $f(\mathbf{x}) = \frac{1}{2}\|\mathbf{A}\mathbf{x} - \mathbf{b}\|_2^2$ as the differentiable (but not strongly convex) part and $\alpha g(\mathbf{x}) = \frac{\alpha\lambda_1}{2}\|\mathbf{x}\|_2^2 + \alpha\lambda_2\|\mathbf{x}\|_1$ as the closed convex but non differentiable part, one has $\nabla f(\mathbf{x}) = \mathbf{A}^\top(\mathbf{A}\mathbf{x} - \mathbf{b})$ and, by identification with $g'(\mathbf{x}) + \frac{c}{2}\|\mathbf{x}\|_2^2 + \langle \mathbf{a}, \mathbf{x} \rangle + \gamma$ with $g'(\mathbf{x}) = \alpha\lambda_2\|\mathbf{x}\|_1, c = \alpha\lambda_1, \mathbf{a} = \mathbf{0}, \gamma = 0$, $\text{prox}_{\alpha g}(\mathbf{x}) = \text{prox}_{\frac{\alpha}{\alpha\lambda_1+1}\lambda_2\|\cdot\|_1}(\frac{\mathbf{x}}{\alpha\lambda_1+1}) = \mathcal{T}_{\frac{\alpha\lambda_2}{\alpha\lambda_1+1}}(\frac{\mathbf{x}}{\alpha\lambda_1+1})$.

- (*V-FISTA2*)

$$\begin{cases} \mathbf{x}^{k+1} &= \mathcal{T}_{\frac{\lambda_2/L_2}{\lambda_1/L_2+1}}\left(\frac{\mathbf{y}^k - \frac{1}{L_2}(\mathbf{A}^\top \mathbf{y}^k - \mathbf{b})}{\frac{\lambda_1}{L_2}+1}\right) = \mathcal{T}_{\frac{\lambda_2}{\lambda_1+L_2}}\left(\frac{L_2\mathbf{y}^k - (\mathbf{A}^\top \mathbf{y}^k - \mathbf{b})}{\lambda_1+L_2}\right) \\ \mathbf{y}^{k+1} &= \mathbf{x}^{k+1} + \left(\frac{\sqrt{\kappa_2}-1}{\sqrt{\kappa_2}+1}\right)(\mathbf{x}^{k+1} - \mathbf{x}^k), \end{cases}$$

with $L_2 = \|\mathbf{A}\|_2^2$, $\kappa_2 = L_2/\sigma$, and $\sigma = \lambda_1$.

One notices the only difference between *V-FISTA* and *V-FISTA2* occurs in the second line, with $\kappa_2 \neq \kappa$.

Figure 1: $F(\mathbf{x}^k) - F_{\text{opt}}$ in log-scale along the y-axis for the first 100 iterations of each of the methods with all-zeros vectors and a constant stepsize.

As can be observed in Fig. 1, the V-FISTA methods worked the best, with a slight improvement in V-FISTA which does not follow the theory. The four first elements are:

- (-0.40403765 0.18475212 0.97264407 -0.99645397]
- (-0.43969331 0.01974521 1.42280231 -0.87819581)
- (-0.4319773 0.02881602 1.43373682 -0.9066518)
- (-0.43210834 0.0295975 1.43437285 -0.90583213)
- (-0.43210892 0.02959727 1.43437048 -0.9058291)

for the Ground truth, and the four methods, PG, FISTA, V-FISTA, V-FISTA2, respectively.

3 Part 2 - Exercise 1 - slide 41

$$\min_{\mathbf{x} \in \mathbb{R}^{30}} \sqrt{\mathbf{x}^\top \mathbf{Q} \mathbf{x} + 2\mathbf{b}^\top \mathbf{x} + c} + 0.2 \|\mathbf{D} \mathbf{x} + \mathbf{1}\|_1,$$

where $\mathbf{Q} \in \mathbb{R}^{30 \times 30}$, $\mathbf{b} \in \mathbb{R}^{30}$, $c \in \mathbb{R}$, $\mathbf{D} \in \mathbb{R}^{10 \times 30}$. The matrix \mathbf{Q} is positive definite.

One has $f(\mathbf{x}) = \sqrt{\mathbf{x}^\top \mathbf{Q} \mathbf{x} + 2\mathbf{b}^\top \mathbf{x} + c}$ and $g(\mathbf{x}) = 0.2 \|\mathbf{D} \mathbf{x} + \mathbf{1}\|_1$.

Hence, $\nabla f(\mathbf{x}) = \frac{\mathbf{Q}\mathbf{x} + \mathbf{b}}{\sqrt{\mathbf{x}^\top \mathbf{Q} \mathbf{x} + 2\mathbf{b}^\top \mathbf{x} + c}}$ and $\text{prox}_{\alpha g}(\mathbf{x}) = \mathbf{x} + \mathbf{D}^\top (\mathcal{T}_{0.2\alpha}(\mathbf{D} \mathbf{x} + \mathbf{1}) - \mathbf{D} \mathbf{x} - \mathbf{1})$.

- (a) [TODO: Write in matrix format with Schur complement.]
- (b) [TODO: Use Cholesky factorization and prove it is a norm.]
- (c)

- (Proximal gradient):

$$\begin{aligned} \mathbf{x}^{k+1} &= \text{prox}_{\frac{1}{L_f} g}(\mathbf{x}^k - \frac{1}{L_f} \nabla f(\mathbf{x}^k)) \\ &= \mathbf{x}^k - \frac{1}{L_f} \nabla f(\mathbf{x}^k) + \mathbf{D}^\top \left(\mathcal{T}_{\frac{0.2}{L_f}} \left[\mathbf{D}(\mathbf{x}^k - \frac{1}{L_f} \nabla f(\mathbf{x}^k)) + \mathbf{1} \right] - \mathbf{D}(\mathbf{x}^k - \frac{1}{L_f} \nabla f(\mathbf{x}^k)) - \mathbf{1} \right) \\ &\stackrel{(*)}{=} \mathbf{D}^\top \left(\mathcal{T}_{\frac{0.2}{L_f}} \left[\mathbf{D}(\mathbf{x}^k - \frac{1}{L_f} \nabla f(\mathbf{x}^k)) + \mathbf{1} \right] - \mathbf{1} \right) \\ &= \mathbf{D}^\top \left(\mathcal{T}_{\frac{0.2}{L_f}} \left[\mathbf{D}(\mathbf{x}^k - \frac{1}{L_f} \frac{\mathbf{Q}\mathbf{x}^k + \mathbf{b}}{\sqrt{(\mathbf{x}^k)^\top \mathbf{Q} \mathbf{x}^k + 2\mathbf{b}^\top \mathbf{x}^k + c}}) + \mathbf{1} \right] - \mathbf{1} \right) \end{aligned}$$

(*) If $\mathbf{D}^\top \mathbf{D} = \mathbf{I}$ (true for the provided data in the numerical example).

- (FISTA): [TODO:]

[TODO: Lipschitz constant analytical solution.]

4 Part 2 - Exercise 3 - slides 71-72

Given a set of data points $\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_n \in \mathbb{R}^d$ and corresponding labels y_1, y_2, \dots, y_n . The soft margin SVM problem is given by

$$\min \left\{ \frac{1}{2} \|\mathbf{w}\|_2^2 + C \sum_{i=1}^n \max \{0, 1 - y_i \mathbf{w}^\top \mathbf{x}_i\} \right\}$$

(a)

(b)

5 Part 3 - Exercise 2 - slides 35-36
